**ABSTRACT**

A new method for one pot synthesis of Hantzsch 1,4-dihydropyridines was achieved by the reaction of aromatic aldehydes, ethyl acetocetate and ammonium acetate at 80 °C in the presence of an isopoly tungstate, tetrabutylammonium hexatungstate [TBA][WO₄]₂, as an effective and environmentally friendly catalyst. An important advantage of this catalyst is the ease of separating it from the reaction mixture, as well as the fact that it could be recycled a number of times.

**Keywords:** tetrabutylammonium hexatungstate [TBA][WO₄]₂, Hantzsch, 1,4-dihydropyridines, solvent-free conditions

**INTRODUCTION**

Dihydropyridines are of importance in biological systems as a class of useful drugs, particularly as anti-oxidants. Some of the representative compounds of this class possess acaricidal, insecticidal, bactericidal and herbicidal activities. Dihydropyridine drugs, namely nifedipine, nicardipine and amlodipine, are cardiovascular agents for the treatment of hypertension. A number of dihydropyridine derivatives are employed as potential drug candidates for the treatment of congestive heart failure. In human body the main metabolic route of dihydropyridine drugs involves their oxidation to pyridines catalyzed by cytochrome-450 in liver. Recently, dihydropyridines are used as organocatalysts for asymmetric reactions such as hydrogenation of quinolines in the synthesis of alkaloids, asymmetric reductive amination of aldehydes and hydrogenation of α,β-unsaturated aldehydes and ketones.

1,4-Dihydropyridines are generally synthesized by Hantzsch reaction which involves the condensation of aldehydes, β-ketoester and ammonia or ammonium acetate. A number of improved methods have been reported in the literature for this condensation which involve the use of microwave irradiation in ionic liquid, trifluoroethanol, AlCl₃, 6H₂O, K₂CO₃, PPh₃, silica gel/NaHSO₄. Many of these procedures suffer from lack of selectivity, unsatisfactory yields, being costly, toxicity of the reagents, or required special conditions. To avoid these limitations, the discovery of a new and efficient catalyst with high catalytic activity, short reaction time, recyclability and simplicity reaction working-up for the synthesis of 1,4-dihydropyridines is of prime interest.

Polyoxometalates (POMs), constituting a large class of metal oxide molecules, are known to have a variety of sizes, structures, electrochemical properties, and chemical reactivities. POMs has been extensively studied because they have many practical applications such as catalysis, molecular materials, and corrosion inhibition. In recent decades, uses of some POMs as catalysts for fine organic synthetic processes have been developed and are important for industries related with fine chemicals, including flavors, pharmaceuticals and food industries.

Prompted by these findings and interest on the development of novel synthetic methodologies in organic reactions, in this paper a solvent-free synthesis of Hantzsch 1,4-dihydropyridines catalyzed by tetrabutylammonium hexatungstate [TBA][WO₄]₂, an isopoly tungstate, as green and effective catalyst is reported (Scheme 1).

**EXPERIMENTAL**

**Chemicals and apparatus**

All chemicals were available commercially and used without additional purification. The catalyst was synthesized according to the known literature. Meltng points were recorded on an electrothermal type 9100 melting point apparatus. The IR spectra were recorded using a 4300 Shimadzu spectrophotometer at KBr disks. The 1H NMR (400 & 500 MHz) spectra were recorded with Bruker 400 & 500 spectrometers.

**Synthesis of tetrabutylammonium hexatungstate [TBA][WO₄]₂**

A mixture of sodium tungstate dihydrate, Na₂WO₄.2H₂O (99%, 0.1 mol, 33 g), acetic anhydride (40 ml) and NN-dimethylformamide (30 ml) is heated at 100 °C for 3 h to obtain a white cream. Then a solution of acetic anhydride (20 ml) and HCl (12 N, 18 ml) in NN-dimethylformamide (DMF) (50 ml) is added with stirring, and the resulting mixture is filtered off to eliminate the undissolved white solid. A solution of tetrabutylammonium bromide (0.047 mol, 15.1 g) in methanol (50 ml) is added with rapid stirring to give a white precipitate. This suspension is stirred for 5 min and the product is filtered. Recrystallization from a minimum amount of hot dimethyl sulfoxide (DMSO) gives colorless diamond-shaped crystals.

**General procedure for the synthesis of 1,4-dihydropyridines**

In a 50 ml round-bottom flask, an aromatic aldehyde 1a-d (2 mmol), ethyl acetocetate 2 (4 mmol) and ammonium acetate 3 (2 mmol) were stirred in presence of [TBA][WO₄]₂ (0.04 g) in solvent-free condition at 80 °C for 15-25 min. The progress of the reaction was monitored by TLC. After completion of the reaction, the reaction mixture was cooled to room temperature and then hot ethanol was added. The catalyst was separated by filtration, dried and reused in next reactions. Ethanol was removed and cold water was then added. The product was extracted with ethyl acetate, washed with 10% NaHCO₃ solution, dried over anhydrous Na₂SO₄, concentrated under vacuum and then filtered in ice bath for a few minutes. The crude product was collected and recrystallized from ethanol to give pure 1,4-dihydropyridine derivatives.

RESULTS AND DISCUSSION

In order to optimize the reaction conditions, the synthesis of diethyl 2,6-dimethyl-4-phenyl-1,4-dihydropyridine-3,5-dicarboxylate 4a was used as a model reaction. Therefore, a mixture of benzaldehyde (2 mmol), ethyl acetoacetate (4 mmol), and ammonium acetate (2 mmol) was heated on the oil bath under various reaction conditions.

The efficiency of the reaction is mainly affected by the amount of [TBA]_4[W_6O_19]_5^- in the presence of [TBA]_4[W_6O_19]_5^- in solvent-free conditions (Table 3). It was observed that yield is a function of temperature, so the yield increased as the reaction temperature was raised in solvent-free conditions (Table 3). In other studies, all reactions carried out at 80 °C in the presence of 0.04 g of [TBA]_4[W_6O_19]_5^- under solvent-free conditions.

To show the generality of this method, the optimized system used for the synthesis of other 1,4-dihydropyridine derivatives with various aromatic aldehydes, ethyl acetoacetate and ammonium acetate (Table 4). In all cases the expected products were obtained in excellent yields in short reaction times.

Also, the reaction was carried out in various solvents. As shown in Table 2, in comparison to conventional methods the yields of the reaction under solvent-free conditions are higher and the reaction times are shorter.

* Aryl aldehyde (2 mmol), ethyl acetoacetate (4 mmol), ammonium acetate (2 mmol), [TBA][W$_6$O$_{19}$] (0.04 g) at 80°C in solvent-free conditions.

$^a$ All the products were characterized by IR spectral data and comparison of their melting points with those of authentic samples. Also, the structures of some products were confirmed by $^1$H NMR spectral data.

$^c$ Isolated yields.
Reusability of the catalyst was also investigated. The catalyst was recovered according to the procedure mentioned in experimental section and reused for next reactions. The obtained results are summarized in Table 5. As it is shown in this table, the catalyst could be used at least three times without significant reduction in its activity.

* Isolated yields

A reaction mechanism is proposed in Scheme 2. Based on Davoodnia’s suggestion, [TBA]$_2$[W$_{18}$O$_{49}$] can play a dual role. It is proposed that the tetrabutylammonium ion [(n-Bu)N$^+$] induces polarization of carbonyl groups. On the other hands, terminal oxygen atoms or the bridging oxygen atom in polyoxometalate anion, W$_{18}$O$_{49}$$^{2-}$, are slightly basic and can promote the reactions. Therefore, [TBA]$_2$[W$_{18}$O$_{49}$] can activate the reactants and also some intermediates in this reaction. Therefore, as shown, it is proposed that [TBA]$_2$[W$_{18}$O$_{49}$] facilitates the formation of the intermediates [I] and [II] that then react together to give the final products 4a-i.

**Scheme 2.** Proposed mechanism for the formation of 1,4-dihydropyridines in the presence of [TBA]$_2$[W$_{18}$O$_{49}$] as catalyst

**CONCLUSIONS**

In conclusion, in this paper a new catalytic method for the synthesis of Hantzsch 1,4-dihydropyridines using aryl aldehydes, ethyl acetoacetate and ammonium acetate in the presence of [TBA]$_2$[W$_{18}$O$_{49}$] as catalyst has been reported. Good to excellent yields, short reaction times, simple operation and easy work-up are some advantages of this protocol. The catalyst can be recycled after a simple work-up, and used at least three times in the reactions without substantial reduction in its catalytic activity.
