ABSTRACT

In this paper, 2-hydrazino-6-methoxy-1,3-benzothiazole was introduced into diethylenetriamine pentaacetic (DTPA) by acylation reaction. The corresponding non-ion Gd(III) complex holding promise of a single molecule magnetic resonance imaging (MRI) contrast agent was obtained by treating this ligand with GdCl₃·6H₂O. The efficacy of the contrast agent was assessed by measuring the longitudinal relaxivity (r₁), the r₂ of Gd(III)-DTPA-bisbenzothiazole hydrazide was up to 6.44 mM⁻¹s⁻¹, which was 1.8 times higher than that of the analogous MRI contrast agent Gd(III)-DTPA (r₂ = 3.64 mM⁻¹s⁻¹) in commercial use. In addition, in vitro MR images on a 0.5 T magnetic field exhibited a remarkable enhancement of signal contrast for Gd(III)-DTPA-bisbenzothiazole hydrazide than Gd(III)-DTPA. These results demonstrate that this non-ion Gd(III) complex acts as a potentially MRI contrast agent.

Keywords: MRI contrast agent; benzothiazole; DTPA derivative; gadolinium complex; relaxivity

INTRODUCTION

Over forty years later, magnetic resonance imaging (MRI) has become one of the most powerful tool in preclinical research and in the clinical diagnosis of various diseases around the world, due to its especially advantageous: high spatial (<0.1 mm) and temporal resolutions, 3-dimensional anatomical images, non-invasive (lack of ionizing radiation), deep tissue penetration and excellent soft tissue contrast and multiple contrast mechanisms. In MRI, image contrast can be generated by differences in tissue water content, water relaxation times, flow, or diffusion. Unfortunately the image contrast is often insufficient for diagnostic purposes. Contrast can be enhanced through the addition of an exogenous MRI contrast agents (CAs) to increase the relaxation rates of water protons in tissue in which the agent accumulates. Most commonly, this is a paramagnetic chelate that shortens the relaxation times of water molecules it encounters. At present, the clinical utility of MRI contrast agents is well established. Annually, at our medical institutions more than 50% of MRI scans were aided by contrast agents to diagnose disease. Therefore, many research groups around the world have been studying MRI contrast agents. To date, more than nine types of the ligand of paramagnetic metal ion-chelate complexes have been approved by Food and Drug Administration (FDA) for clinical application. A vast body of literature exists describing ligands for Gd(III), and the majority are polyaminopolycarboxylate ligands, like Gd-DTPA (DTPA=diethylenetriamine pentaacetic acid), Gd-DOTA (DOTA=1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid), Gd(HP-DO3A) (HP-DO3A=10-(2-hydroxypropyl)-1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid), etc. However, most contrast agents have non-specific extracellular distribution and the disadvantages of low relaxivity, low tissue specificity, and rapid clearance. Moreover, most of the MRI contrast agents suffer low T₁ relaxivity, which is still far from expectation for highly sensitive MRI. These drawbacks have hindered the further development of MRI as a diagnostic tool. Therefore, an ideal MRI contrast agent should be designed as the tissue or organ-targeting materials with high relaxivity, low toxicity and side effects, suitable long intravascular duration and excretion time, and high contrast enhancement with low dose, in vivo, all coupled to low overall cost.

Benzothiazole and its derivatives have been extensively investigated due to the high biological activity such as antimicrobial, anti-inflammatory and anticancer activity. Based on the previous work, a great deal of research groups devoted to develop various benzothiazole derivatives with high antitumor activity in the past two decades. The above observations prompted us to design and synthesize a new gadolinium complex incorporating benzothiazole unit by the straightforward and efficient reaction of the bicyclic anhydride of diethylenetriaminepentaacetic acid (DTPAA) with 2-hydrazino-6-methoxy-1,3-benzothiazole (Scheme 1). The longitudinal relaxation time (T₁) was measured, and spin–lattice relaxivity values (r₁) of this Gd(III) complex was higher than that of Magnevist (Gd(III)-DTPA). In vitro MR images on a 0.5 T magnetic field exhibited that proton signal intensity increased with Gd(III) complex concentration and a remarkable enhancement of signal contrast for Gd(III)-DTPA-bisbenzothiazole hydrazide than Gd(III)-DTPA. Water-solubility tests showed that the solubility of the Gd(III)-L complex in water is largely and up to 0.8 g mL⁻¹ at room temperature. These results showed that the complex is a prospective magnetic resonance imaging agent.

EXPERIMENTAL

GENERAL

Melting points were determined on a digital apparatus and are uncorrected. TLC analysis was performed on glass sheets coated with Merck silica gel 60 F₂₅₄. Compounds were visualized by I₂, steam or UV-vis. ¹H-NMR spectra were recorded on Bruker AV-400 spectrometers respectively. Chemical shift(s) were reported in parts per million from internal standard tetramethylsilane (TMS). Coupling constants (J) were measured in Hertz. Multiplicity was reported as follows: s (singlet), d (doublet), t (triplet), m (multiplet) and combination of these signals. Column chromatographies were performed on silica gel 60 (200-300 mesh). IR spectroscopy recorded with a Nicolet 380 FT-IR. Elemental analyses were determined on a Vario EL III (Elementar), Mass spectra were obtained on an Agilent6110 (Agilent Technologies, USA). The solvent longitudinal relaxation time (T₁) for gadolinium complexes in distilled water was determined by a standard inversion-recovery sequence on the MicroMR imaging & analyzing system at 32 °C and 0.5 T (Niumag Technology Co., Ltd., Suzhou, China). MARS5 microwave digestion system.

Scheme 1. Synthesis of ligand(H₃L) and complex(Gd(III)-L)
RT1001-RT1002 ultrasonic cleaning machine.
All reagents and solvents were analytical grade from commercial suppliers and used without further treatments unless otherwise stated. Reactions were carried out under N\textsubscript{2} atmosphere, unless otherwise noted.

SYNTHESIS

Concentration of 2-hydradino-6-methoxy-1,3-benzothiazole (2)
Concentrated hydrochloric acid (8.6 mL, 36%, 0.1 mol) was added dropwise with stirring to hydrazine hydrate (11.5 mL, 85%, 0.2 M) at 0°C followed by ethylene glycol (30 mL), there after 2-amino-6-methoxy-1,3-benzothiazole (1) (9 g, 0.05 mol) was added in portions and the resultant mixture was refluxed for 12 h and cooled at room temperature. The reaction progress was monitored by TLC using toluene:ethanolacetonitrile (v:v = 75:25) as mobile phase. The reaction mixture was filtered and resulting precipitate was washed with distilled water, then recrystallized from ethanol to give 2 as a reddish brown solid. Yield: 6.73 g (60 %); mp 176-177.5°C. FT-IR (KBr pellet): 3200-3450 (NH\textsubscript{3}), 1628 (C=N), 1448 (thiazole) cm\textsuperscript{-1}; 1H NMR (400 MHz, CDCl\textsubscript{3}, δ/ppm): 1.44 (bs, 6H, 2×O-CH\textsubscript{3}), 2.30 (s, 4 H, 2×-CONH-), 7.43 (d, J=7.8 Hz, 2 H), 7.40 (d, J=7.1 Hz, 1 H), 7.16 (d, J=2.4 Hz, 1 H), 1.74 (d, J=8.8 Hz, 1 H). Anal. Calcd for C\textsubscript{12}H\textsubscript{8}N\textsubscript{2}O\textsubscript{2}S: C, 37.16; H, 3.36; N, 22.70. Obsd: C, 37.04; H, 3.29; N, 22.66.

Synthesis of diethylenetriamine-N,N\textsubscript{2},N\textsuperscript{3}-bis(acetyl-6-methoxy-1,3-benzothiazole-2-hydradino) - N,N\textsubscript{2},N\textsuperscript{3}-Triacetic acid (DTPA-bisbenzothiazole Hydrazide) (H\textsubscript{L})
DTPA dihydrate (1.428 g, 4.0 mmol) and 2-hydradino-6-methoxy-1,3-benzothiazole (2) (1.56 g, 8.0 mmol) were dissolved in 20 mL dry pyridine and stirred at 60°C for 4 h under N\textsubscript{2} atmosphere. After removal of the solvent, the solid residue was washed with ice water and dried in water bath, then recrystallized from methanol:water (v:v = 3:1) to give H\textsubscript{L} as a yellowish solid. Yield: 2.4g (80 %); mp 138-140°C. FT-IR (KBr pellet): 3404, 3054, 2968, 2883, 1479, 1385, 1300, 1232, 1133, 1092, 1046, 966, 842 cm\textsuperscript{-1}. Anal. Calcd for C\textsubscript{54}H\textsubscript{38}N\textsubscript{14}O\textsubscript{12}S\textsubscript{2}: C, 48.89; H, 5.48; N, 15.97. Obsd: C, 48.80; H, 5.37; N, 15.85. FT-IR spectrum of the ligand (H\textsubscript{L}) was shown in Fig. 1a.

RESULTS AND DISCUSSION

As mentioned previously, because of the favorable pharmacological properties of benzothiazole compounds, we have produced the corresponding DTPA analogues containing benzothiazole. The synthetic scheme of ligand (DTPA-bisbenzothiazole hydrazide, H\textsubscript{L}) is shown in Scheme 1. The structure of ligand was characterized by FT-IR, ES-API-MS, 1H NMR and elemental analysis. 1H NMR, FT-IR were conformed with the structure of diethylenetriamine-N,N\textsubscript{2},N\textsuperscript{3}-bis(acetyl-6-methoxy-1,3-benzothiazole-2-hydradino) - N,N\textsubscript{2},N\textsuperscript{3}-triacetic acid (DTPA-bisbenzothiazole hydrazide, H\textsubscript{L}). The 1H NMR spectrum of the ligand (H\textsubscript{L}) was shown in Fig. S2. The 1H NMR spectra showed the characteristic peaks of N\textsubscript{2}CH\textsubscript{2}OH groups of DTPA structure and benzyl groups of benzothiazole structure, indicating that DTPA was covalently bound to benzothiazole. The ES-API-MS spectra(Fig. S3) revealed that the molecular ion peaks were in accordance with the given structure of it. ES-API-MS(positive mode): m/z [M+H]\textsuperscript{+} Calcd. 748.21 Da; Obsd. 748.3 Da. The Gd(III)-L complex was prepared by reacting the ligand with stoichiometric amounts of the GdCl\textsubscript{3}-6H\textsubscript{2}O in high yield. Water-solubility tests showed that the solubility of the Gd(III)-L complex in water is largely and up to 0.8 g mL\textsuperscript{-1} at room temperature. According to reported method\textsuperscript{20}, Gd(III)-DTPA-bisbenzothiazole hydrazide was dissolved in distilled water at concentration of 10.0 mM, then the solution of Gd(III) complex was added into oxalic acid (C\textsubscript{2}O\textsubscript{4}) and the molar amount 10 times than that of Gd(III) complex, the mixed solution was stand for 30 days under room temperature. After careful observation, the mixed solution was clear and transparent. It illustrated that this Gd(III) complex is preliminarily stable in vitro. In the FT-IR spectra of the ligand(Fig. 1a), strong and broad absorption peaks at 3446 cm\textsuperscript{-1} were attributed to OH and NH. The peaks at 1725 cm\textsuperscript{-1} (A) and 1660 cm\textsuperscript{-1} (B), were attributed to COOH and vCONH, respectively. For Gd(III)-L complex(Fig. 1b), the band (A) disappeared in the complex, showing that the carboxyl proton dissociates and the oxygen atom was coordinated to metal. The band (B) was shifted to 1610 cm\textsuperscript{-1}, suggesting that the oxygen atom of the amide is coordinated to metal\textsuperscript{21}. The ligand provided three nitrogen atoms, five carboxyl oxygen atoms bonding to metal.

In vitro imaging effect of Gd(III)-DTPA-bisbenzothiazole hydrazide is visualized by FLASH images in phantoms. Multislice spin echo (MSE) sequence(TR=100 ms, TE=12.5 ms, NS=32, Slice thickness=3.0 mm) on the MR23-060H-I imaging & analyzing system(0.5 T) was employed for the acquisition of the in vitro imaging. The effects of paramagnetic ions on the T1 relaxation nuclear spins were first formulated by Bloembergen and Solomon and subsequently extended by several authors\textsuperscript{22-25}. On the basis of this theory, the longitudinal relaxation time T1 in the presence of Gd complex is given by Eq. (1):

\[
1/T1_{\text{obsd}} = 1/T1_{\text{sp}} + r\gamma\text{[M]}
\]

where \((1/T1_{\text{obsd}})\) is the observed solvent relaxation rate in the presence of a paramagnetic species, \((1/T1_{\text{sp}})\) is the solvent relaxation rate in the absence of a paramagnetic species, \([\text{M}]\) denotes the concentration of gadolinium ion in the measured solution, and \(r\) is the relaxation of the agent in a unit of mm\textsuperscript{-1} s\textsuperscript{-1}, which is the most important parameter in evaluating a contrast agent and was calculated from the slope of the plots of \((1/T1_{\text{obsd}})\) versus the Gd concentrations. Fig. 2 illustrates that the relaxivity of gadolinium complex produced in our present work was 6.44 mm\textsuperscript{-1} s\textsuperscript{-1}, which was 1.8 times higher than that of the

Fig. 1 FT-IR spectrum of H\textsubscript{L}(a) and Gd(III)-L complex (b)
analogous MRI contrast agent Gd(III)-DTPA($r_1 = 3.64$ mM$^{-1}$·s$^{-1}$) in commercial use at the same condition. Possible explanations for increased relaxivity, relative to clinical contrast agent Gd(III)-DTPA, include: (a) increasing the molecule size by introducing an aromatic group causes a decrease in rotational correlation rate (relatively long rotational correlation time); (b) an increase in the number of outer sphere coordinated water molecules via hydrogen bonds to the nitrogen atoms of the thiazenaole groups; (c) hydrophilic hydrazide group may be able to transmit water molecule from outer-sphere to the inner-sphere easily.

**Fig. 2** Plots of $1/T_1$ vs the Gd concentrations of Gd(III)-L complex as well as Gd-DTPA in water solution

The Fig. 3 showed in vitro MR images prepared by Gd(III)-DTPA(b) and Gd(III)-L (a) solutions in phantoms. It was seen that proton signal intensity increased with Gd(III) complex concentration. Besides, the imaging effect of Gd(III)-L was superior to that of Gd(III)-DTPA in the same condition.

**CONCLUSIONS**

In summary, We have successfully synthesized a new gadolinium complex(Gd(III)-L complex by a simple and efficient reaction. The longitudinal relaxivity ($r_1$) of this Gd(III)-L complex is higher than that of Gd(III)-DTPA, and the in vitro imaging effect of Gd(III)-L was superior to that of Gd(III)-DTPA in the same condition, which makes it possible to reduce the risk of the toxicity by lowering the dose of Gd(III) chelates. Thus Gd(III)-L might be considered as a potential MRI contrast agent.
