Abstract

In this paper, the notion of generalized preopen compactness is introduced and connections to other several types of compactness are discussed. In addition, new separation axioms are established.

Keywords : *Generalized preopen set, generalized preopen compactness.*

2004 AMS Subject Classification. *54C08, 54H05.*

1. Introduction

Let (X, τ) be a topological space (or simply, a space) and $A \subseteq X$. Then A is α -open or α -set [14, 12] (resp., *semi-open* [2], *semi-closed* [2], *pre-open* [11], *preclosed* [11], *semi-preopen* [2], *generalized closed* [9]) if $A \subseteq \text{int}(\text{cl}(\text{int}(A)))$ (resp., $A \subseteq \text{cl}(\text{int}(A))$, $\text{int}(\text{cl}(A)) \subseteq A$, $A \subseteq \text{int}(\text{cl}(A))$, $\text{cl}(\text{int}(A)) \subseteq A$, $A \subseteq \text{cl}(\text{int}(\text{cl}(A)))$, $\text{cl}(A) \subseteq U$, for every open set U containing A), where $\text{int}(\)$ and $\text{cl}(\)$ are the interior and closure operations, respectively. A is *regular-open* if $A = \text{int}(\text{cl}(A))$ [16]. Complements of regular-open sets are called *regular-closed*. A is *semi-regular* [11] if it is both semi-open and semi-closed. A is *interior closed* [7] if $\text{int}(A)$ is semi-closed. A is an *A-set* [16] if $A = U \cap C$, where U is an open set and C is a regular closed set. It is known that an A-set is semi-open [16]. A is a *B-set* [4] if $A = U \cap C$ where U is an open set and C is semi-closed. A is *locally closed* if A is open in its closure [4]. A is an *AB-set* [4] if $A = U \cap C$, where U is open and C is semi-regular. Equivalently, A is an locally closed set if $A = U \cap C$, where U is open and C is closed. Clearly every A-set is a locally closed set and every locally closed set is a B-set. Since regular closed sets are semi-regular and since semi-regular sets are semi-closed, the following implications are obvious:

$$A - \text{set} \Rightarrow AB - \text{set} \Rightarrow B - \text{set},$$

but none of them of course is reversible [4]. Moreover, since the intersection of an open set and a semi-regular set is always semi-open, every AB-set is semi-open.

A space (X, τ) is called a *partition space* if every open subset of X is closed, see [4]. (X, τ) is called *hyper connected* if every open subset of X is dense. (X, τ) is called *extremely disconnected* (simply, ED) if every open subset of X has an open closure or equivalently if every regular closed set

is open. Spaces that contain two disjoint dense subsets are called *resolvable*. (X, τ) is called *strongly irresolvable* [6] if every open subspace of X is irresolvable, i.e. it can not be represented as a disjoint union of two dense subsets. In [5], it has been pointed out that a space is strongly irresolvable if and only if every preopen set is semi-open. (X, τ) is said to be *P-closed* [3] (resp., *quasi-H-closed* (simply, QHC)) if every preopen (resp., open) cover of X has a finite subfamily the preclosures (resp., closures) of whose members cover X . (X, τ) is said to be *strongly compact* [10] if every preopen cover has a finite subcover. (X, τ) is called *nearly compact* [13] if every cover of X by regular open sets has a finite sub cover. Thompson [15] introduced the class of *S-closed spaces*, where a space X is called S-closed if every semi-open cover of X has a finite subfamily the closures of whose members cover X , or equivalently, if every regular closed cover of X has a finite subcover. (X, τ) is said to be *strongly p-regular* [5] (resp., *p-regular*, *almost p-regular*) if for each point $x \in X$ and each pre-closed set (resp., closed set, regular closed set) F such that $x \notin F$, there exist disjoint pre-open sets V and U such that $x \in U$ and $F \subseteq V$. (X, τ) is called *s-closed*, if every semi-open cover has a finite subfamily the semi-closures of whose members cover X .

Throughout this paper, $(X, \mathfrak{S})$ and (Y, δ) stand for topological spaces with no separation axioms assumed unless otherwise mentioned.

The fundamental notion of *generalized open sets* was introduced and explored by several authors. In recent years a number of other generalizations of open sets have been studied. Generalized open sets play a very important role in General Topology and they are now the research topics of many topologists worldwide. In fact, a significant theme in General Topology and Real analysis concerns the variously modified forms of continuity, separation axioms etc. by utilizing generalized open sets. One of

the most well known notions and also an inspiration source is the notion of generalized preopen sets introduced in [1]. This class is a superset of the class of semi-closed sets, the class of α -sets, the class of AB-sets, the class of A-sets and the class of semi-regular sets. Moreover, these investigations lead to solve the problem of finding the continuity dual of some generalized continuous functions in order to have a decomposition of continuity.

This paper is divided as follows: In Section 2, the concept of generalized preopen set is introduced and explored. Properties and connections to other well-known weak and generalized open sets are discussed. Moreover, a characterization of closed and open sets is provided and spaces are studied. In Section 3, generalized preopen compactness is introduced and connections to other types of compactness are discussed. Finally, Section 4 is devoted to discussing new separation axioms defined via generalized preopen sets.

2. Generalized preopen sets in certain spaces

We begin this section by recalling the concept of generalized preopen set and some related results from [1].

Definition 1. [1] A subset A of a space X is generalized preopen (simply, *gpo*-) set if $cl(A) \subseteq U$, whenever U is a preclosed subset such that $U \supseteq A$. Complements of *gpo*- sets are called generalized preclosed (simply, *gpc*-) sets.

By $gpc(X, \tau)$ (resp., $gpc(X, \tau)$), we denote the collection of all *gpc* (resp., *gpc*) -sets in X .

Lemma 1. [1] A subset A of a space X is *gpc* if and only if for every preopen set V contained in A , $V \subseteq \text{int}(A)$.

We remark that if A and B are gpo- sets, then $A \cap B$ need not be a gpo-set, while arbitrary unions of gpo-sets are gpo-sets.

Example 1. Since $(1, 3]$, as a subspace of the reals with the standard topology, is a gpo- set but not preopen, and $(0,1]$ with the indiscrete topology is preopen but not a gpo- set.

Example 2. Let $X = \{a, b, c, d\}$ and

$$\tau = \{\phi, \{a\}, \{b\}, \{a, b\}, \{b, c, d\}, \{a, c, d\}, \{c, d\}, X\}.$$

Then X is an ED space, $\{c\}$ is a preclosed set that is not a gpo- set. Moreover, $\{c\}$ is not a regular closed set.

Definition 2. A space (X, τ) is gpo- irresolvable if every preopen set is a gpo- set.

Theorem 1. In a strongly irresolvable space, every semi-open set is a gpo- set.

Theorem 2. If (X, τ) is strongly irresolvable, then it is gpo-irresolvable.

Proof: Let A be a preopen set. Then since X is strongly irresolvable, A is semi-open and by Theorem 2, A is a gpo- set.

The converse of Theorem 2 is not true in general. $A = (-\infty, 1]$ with the leftray topology on the reals is a gpo- set and a preopen set but not semi-open.

The following is a new characterization of open sets.

Theorem 3. [1] A subset $A \subseteq X$ is open if and only if A is a gpo-set and a preopen set.

3. Gpo- compact spaces

Several types of compact spaces were discussed in [3,4,5,8,11]. In this section, gpo-compact notion is introduced and connections to other several well-known types of compactness are discussed.

Definition 3. A space (X, τ) is gpo-compact if every gpo-cover (a cover consisting of gpo- sets) of X has a finite subcover.

Equivalently, (X, τ) is gpo-compact if every gpo-cover of X has a finite subcover. A submaximal space is an example of a gpo-compact space. The proof of the following result follows from the fact that every open set is a gpo-set.

Theorem 4. If (X, τ) is a gpo-compact space, then it is compact.

Since every compact space is nearly compact and a QHC-space, a gpo-compact space is nearly compact and QHC.

Theorem 5. If a space (X, τ) is gpo-irresolvable and gpo-compact, then it is strongly compact.

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a preopen-cover of X . Then since X is gpo-irresolvable, by Theorem 1, $\mathbf{A}$ is a gpo-cover of X and since X is gpo-compact, it has a finite subcover. Thus X is strongly compact.

The converse of Theorem 4 need not be true since a gpo-set need not be preopen. In addition, the notions of gpo-irresolvable and gpo-compact are independent.

Corollary 1. If a space (X, τ) is gpo-irresolvable and gpo-compact, then it is P -closed.

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a preopen cover of X . Since X is gpo-irresolvable, A_α is a gpo-set for all $\alpha \in \Delta$ and $\mathbf{A}$ is a gpo-cover of X . Since X is gpo-compact, it has a finite subcover. Thus $X \subseteq \bigcup_{i=1}^n A_{\alpha_i}$. But $\bigcup_{i=1}^n A_{\alpha_i} \subseteq \bigcup_{i=1}^n pcl(A_{\alpha_i})$, and so X is P-closed.

Since a gpo-set need not be preopen, a P-closed space need not be gpo-irresolvable or gpo-compact.

Corollary 2. *If (X, τ) is P-closed, T_0 and gpo-compact, then it is strongly compact.*

Proof: By Theorem 3, (X, τ) is strongly irresolvable. By Theorem 2, (X, τ) is gpo-irresolvable and by Theorem 5, (X, τ) is strongly compact.

Theorem 6. *If (X, τ) is a gpo-compact space, then it is s-closed.*

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a semi-open cover of X . Then $\mathbf{A}$ is a gpo-cover of X . Since X is gpo-compact, it has a finite subcover such that $X \subseteq \bigcup_{i=1}^n A_{\alpha_i}$. But $\bigcup_{i=1}^n A_{\alpha_i} \subseteq \bigcup_{i=1}^n scl(A_{\alpha_i})$. Thus $X \subseteq \bigcup_{i=1}^n scl(A_{\alpha_i})$, so X is s-closed.

Since an s-closed space is S-closed, a gpo-compact space is S-closed.

Theorem 7. *If a map $f : (X, \tau) \rightarrow (Y, \sigma)$ is gpo-irresolute (resp., gpo-continuous) surjective and K is gpo-compact subset of X , then $f(K)$ is gpo-compact (resp, QHC) in Y .*

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be any gpo- (open) cover of $f(K)$. Since f is gpo-irresolute (resp, gpo-continuous), $A^* = \{f^{-1}(A_\alpha) : \alpha \in \Delta\}$ is gpo-cover of K where K is gpo-compact. Thus it has a finite subcover. That is

$K \subseteq \bigcup_{i=1}^n f^{-1}(A_{\alpha i})$. Since f is gpo-irresolute (gpo-continuous) and surjective, we have $f(K) \subseteq \bigcup_{i=1}^n f(f^{-1}(A_{\alpha i})) \subseteq \bigcup_{i=1}^n A_{\alpha i}$ (resp., $f(K) \subseteq \bigcup_{i=1}^n A_{\alpha i} \subseteq \bigcup_{i=1}^n cl(A_{\alpha i})$). Thus $f(K)$ is gpo-compact (resp., QHC) in Y .

Definition 4. A space (X, τ) is strongly s-compact if for every gpo-cover $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$, there exist $A_{\alpha 1}, A_{\alpha 2}, \dots, A_{\alpha n} \in \mathbf{A}$ such that $X \subseteq \bigcup_{i=1}^n cl(A_{\alpha i})$.

If (X, τ) is gpo-compact, then clearly it is strongly gpo-compact, since $\bigcup_{i=1}^n A_{\alpha i} \subseteq \bigcup_{i=1}^n cl(A_{\alpha i})$ for every $A_{\alpha i} \subseteq X$, $i = 1, 2, \dots, n$.

Definition 5. A space (X, τ) is strongly Ogpo-regular if X has a gpo-cover $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ for all $x \in X$, and for all $A_\alpha(x) \in \mathbf{A}$ such that $x \in A_\alpha(x)$, there exists $U_x \in gpo(X)$ such that $x \in U_x \subseteq cl(U_x) \subseteq A_\alpha(x)$.

Theorem 8. If (X, τ) is strongly gpo-compact and strongly Ogpo-regular, then it is gpo-compact.

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a gpo-cover of X . Then since X is strongly Ogpo-regular, for all $x \in X$, there exists $A_\alpha(x) \in \mathbf{A}$ such that $x \in A_\alpha(x)$ and there exists $U_x \in gpo(X)$ with $x \in U_x \subseteq cl(U_x) \subseteq A_\alpha(x)$. Thus $\{U_x : x \in X\}$ is a gpo-cover of X . Since X is strongly gpo-compact, there exist $U_{x1}, U_{x2}, \dots, U_{xn}$ such that $X \subseteq \bigcup_{i=1}^n cl(U_{xi}) \subseteq \bigcup_{i=1}^n A_{\alpha i}(x)$. Therefore X is gpo-compact.

Corollary 3. If (X, τ) is strongly Ogpo-regular, then it is strongly gpo-compact if and only if it is gpo-compact.

Definition 6. A space (X, τ) is gpo-regular if for every gpo-cover $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ of X and for every $x \in A_\alpha(x) \in \mathbf{A}$, there exists a preopen set U_α such that $x \in U_\alpha \subseteq A_\alpha$.

Theorem 9. If (X, τ) is a gpo-regular and a strongly compact space, then it is gpo-compact.

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a gpo-cover of X . Then since X is gpo-regular, for all $x \in A_\alpha(x)$ there exists $U \in po(X)$ such that $x \in U_\alpha \subseteq A_\alpha$ for all $\alpha \in \Delta$ and so $\{U_\alpha : \alpha \in \Delta\}$ is a preopen cover of X . Since X is strongly compact, then $X = \bigcup_{i=1}^n U_{\alpha i} \subseteq \bigcup_{i=1}^n A_{\alpha i}$. Therefore X is gpo-compact.

The converse of the preceding Theorem need not be true since a preopen set need not be a gpo-set. Moreover, it is clear that the notions of gpo-regular and gpo-irresolvable spaces are independent. The proof of the following result follows immediately from Theorem 8 and Theorem 9.

Corollary 4. If a space (X, τ) is gpo-regular and gpo-irresolvable, then it is gpo-compact if and only if it is strongly compact.

Definition 7. A space (X, τ) is o-regular if for every gpo-cover $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ of X and for every $x \in A_\alpha(x) \in \mathbf{A}$, there exists an open set U , such that $x \in U_x \subseteq cl(U_x) \subseteq A_\alpha(x)$.

Theorem 10. If (X, τ) is o-regular, then it is gpo-compact if and only if it is QHC.

Proof: Let (X, τ) be gpo-compact. By Theorem 7, (X, τ) is a compact space, so it is QHC-space.

Conversely, let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a gpo- cover of X . Since X is o-regular, for every $x \in A_\alpha(x) \in \mathbf{A}$, there exists an open set U such that $x \in U_x \subseteq cl(U_x) \subseteq A_\alpha(x)$. Thus $\{U_\alpha : \alpha \in \Delta\}$ is an open cover of X . Since X is QHC, there exists a finite family such that $X = \bigcup_{i=1}^n cl(U_{\alpha i}) \subseteq \bigcup_{i=1}^n A_{\alpha i}$. Hence (X, τ) is gpo-compact.

Corollary 5. *If (X, τ) is o-regular, then it is gpo-compact if and only if it is s-closed(S-closed, compact, nearly compact).*

Proof : Clearly s-closed (S-closed, compact, nearly compact) imply QHC and by Theorem 10, QHC imply gpo-compact.

Conversely, if (X, τ) is gpo-compact, then by Theorem 7 it is compact and so it is nearly compact and by Theorem 12, it is s-closed. Thus it is S-closed.

Theorem 11. *If (X, τ) is o-regular, then it is QHC if and only if it is strongly gpo-compact.*

Proof: Let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be a gpo-cover of X . Since X is o-regular, for every $x \in A_\alpha(x) \in \mathbf{A}$ there exists an open set U such that $x \in U_x \subseteq cl(U_x) \subseteq A_\alpha(x)$. So $\{U_\alpha : \alpha \in \Delta\}$ is an open cover of X . Since X is QHC, $X \subseteq \bigcup_{i=1}^n cl(U_x) \subseteq \bigcup_{i=1}^n A_{\alpha i}(x)$. Since $\bigcup_{i=1}^n A_{\alpha i} \subseteq \bigcup_{i=1}^n cl(A_{\alpha i})$ for every $A_{\alpha i} \subseteq X, i = 1, 2, \dots, n$, X is strongly gpo- compact.

Conversely, let $\mathbf{A} = \{A_\alpha : \alpha \in \Delta\}$ be an open cover of X . Then $\mathbf{A}$ is a gpo- cover of X and since X is strongly gpo-compact, $X \subseteq \bigcup_{i=1}^n cl(A_{\alpha i}(x))$. Thus X is QHC.

4. Separation axioms via gpo-sets

In this section, several new separation axioms via gpo- sets are introduced.

Connections to other well-known ones are also discussed.

Definition 8. Let (X, τ) be a topological space. Then

(a) (X, τ) is called a **T_{p0} – space** if for each pair of distinct points $x, y \in X$, there is either a gpo- set containing x but not y or a gpo- set containing y but not x .

(b) (X, τ) is called a **T_{p1} – space** if for each pair of distinct points $x, y \in X$, there is a gpo- set containing x but not y , and a gpo- set containing y but not x .

(c) (X, τ) is called a **T_{p2} – space** if for each pair of distinct points $x, y \in X$, there exist gpo- sets U and V such that $x \in U, y \in V$ and $U \cap V = \phi$.

(d) (X, τ) is called a weak regular space if for each closed subset $F \subset X$ and each point $x \notin F$, there exist gpo- sets U and V such that $x \in U, F \subset V$ and $U \cap V = \phi$. A weak regular T_{p1} – Space is called **T_{p3} – space**.

(e) (X, τ) is called a weak normal space if for each pair of disjoint closed subsets F_1 and F_2 of X there exist gpo-sets U and V such that $F_1 \subset U, F_2 \subset V$ and $U \cap V = \phi$. A weak normal T_{p1} – Space is called a **T_{p4} – space**.

It is clear that the T_{p2} condition implies the T_{p1} condition, which in turn implies the T_{p0} condition. Since the notions of open set and gpo-set are independent, weak regularity and regularity are also independent notions.

Theorem 12. If each point $x \in X$ is a gpo-set, then the space (X, τ) is a T_{p1} – Space.

Proof: Let each point of X be a gpo subset of X . If $|X| = 1$, the result is clear. Thus let x and y be distinct points of X . Then $\{y\}$ is a gpo-set, so $X \setminus \{y\}$ is a gpo-set containing x but not y . It follows that (X, τ) is a T_{p1} – Space.

Definition 9. A space X is called completely p -regular if for each closed set $A \subset X$ and each $p \notin A$, there exists a gp -continuous map $f : X \rightarrow I$ such that $f(p) = 1$ and $f(A) = 0$. A completely p -regular T_{p1} -Space is called a $T_{p3\frac{1}{2}}$ -Space.

Definition 10. A space (X, τ) is called completely p -normal if given any two disjoint subsets A and B of X , there exist disjoint gp -sets U and V of X such that $A \subset U$ and $B \subset V$. A completely p -normal T_{p1} -Space is called a T_{p5} -Space.

The proof of the following results follow from the fact that open sets are gp -sets.

Theorem 13. Let (X, τ) be a space. Then every T_i -Space is a T_{pi} -space, for $i = 0, 1, 2, 3, 3\frac{1}{2}, 4, 5$.

Theorem 14. Every $T_{p3\frac{1}{2}}$ -Space is a T_{p3} -Space and every T_{p5} -Space is a T_{p4} -Space.
