CHEMICAL COMPOSITION OF ICE POPS PRODUCED IN A MICROINDUSTRY FROM HIDALGO, MEXICO

COMPOSICIÓN QUÍMICA DE PALETAS CONGELADAS PRODUCIDAS EN UNA MICROINDUSTRIA DE HIDALGO, MÉXICO

ABSTRACT

The chemical composition of water and milk based ice pops produced by a microindustry in Hidalgo, Mexico were determined. Fifteen samples of several flavors were analyzed. The proximate composition was carried out according AOAC techniques. The identification and quantification of fatty acids in the milk based ice pops was performed by Gas Chromatography provided with a flame ionization detector. Water based ice pops did not present a significant nutritional value. Regarding milk based ice pops all samples contained from 6.83 to 12.7% of fat and some samples showed interesting contents of protein (3.55 and 4.21%). The fatty acid profile revealed higher contents of unsaturated fatty acids compared with saturated fatty acids. Trans fatty acids were detected in five of seven milk based samples, representing 20-60% of total fatty acids. Analysis showed that the mixes used to prepare ice pops are different according to their flavor, kind, and amount of fruit which alters their nutritional value and the levels of trans-fatty acids.

Key words: chemical composition, fatty acids, gas chromatography, ice pops.

Este trabajo fue recibido el 11 de Octubre de 2011 y aceptado para ser publicado el 12 de Enero de 2012.

INTRODUCTION

Nowadays, ice cream has been included in the diet of many people around the world due mainly to their sensory properties. In Mexico, ice pops are frozen sweets on a stick (1). Ice pops as well as ice creams are classified according to the base used in their formulation which can be water or milk products. Milk based ice pops are those whose main ingredient is milk, cream or its derivatives. They have a nutritional value due to the contribution of protein, carbohydrates, fat and minerals mainly calcium and vitamins such as B2. The main ingredient of the other variety of ice pops is water. In some cases part of this water is substituted with fruit juice which improves the nutritional value.

Concerning milk based ice pops, fat is one of the most important ingredients because it contributes significantly to physicochemical and sensory properties. The fat content in ice cream is provided primarily by the milk fat, either whole cream, natural butter, anhydrous

butter or oil butter (2). Ice cream also contains, in low proportion, vegetable fat, such as coconut oil, palm, palm kernel or vegetable oil blends (hydrogenated and non-hydrogenated) and other ingredients such as chocolate (2,3). For all ice cream types, fats are the nutrients with the most variable content; therefore, these components make the difference in this kind of food (4-6).

Fat gives adequate texture properties to ice cream, provides a slight scent and acts synergistically with added flavorings, although it produces some decrease in shaking rate. This ingredient also plays an important role in flavor and in the solid structure formation during freezing, establishes the consistency, appearance and resistance to ice cream melting (2,7). During ice cream manufacturing, milk fat can be replaced by vegetable fat, reducing production costs but this affects their final composition and becomes a source of trans fatty acids (TFA) (8). The aim of this work was to provide information about chemical composition of ice pops produced

locally in Hidalgo, Mexico, to know the nutritional value and the fatty acid composition of milk ice pops.

MATERIALS AND METHODS

Samples

Fifteen samples of several flavors made with natural fruits (table 1) were obtained from a microindustry located in Sahagun City in the State of Hidalgo, Mexico. Samples were kept frozen until their analysis.

Proximate analysis

Protein, fat, ash, moisture and fiber content were determined to all samples according to the methodology

established by AOAC (9).

Mineral content

The mineral content was measured only for milk based ice pops. Ca, Mg and P content were determined by Inductively Coupled Plasm Mass Atomic Emission Spectrometry (ICP-MAES). Ashes obtained previously during the proximate analysis were redissolved in 10 mL of concentrated nitric acid and transferred to a volumetric flask. Volume was set to 50 mL with distilled water. The resulting solutions were kept at 4°C in plastic containers until their analysis.

Mineral standard solutions (Perkin Elmer) were

prepared in nitric acid (3%): Ca and Mg 1000 ppm, P 326.6 ppm (table 2). Quantification was carried out in a Spectrophotometer Perkin Elmer, Optima 3000 XL. Wave lengths used were 422.673 nm (Ca), 213.618 nm (Mg) and 259.940 nm (P). Detection limits were Ca, 0.1 mg/L, Mg 0.2 mg/L and P 0.05 mg/L.

Lipid profile of milk based ice pops

The identification and quantification of fatty acids from milk based ice pops were realized by Gas Chromatography with a Flame Ionization Detector.

Lipid extraction and fatty acid methylation

Five grams of each ice pop sample were placed in a test tube adding 3.75 mL of a chloroform-methanol mixture (1:2 v/v). This mixture was shaken in a vortex mixer for one minute followed by the addition of 1.25 mL of chloroform, and then it was shaken again for another minute until total lipid sample separation was achieved. All tubes were centrifuged at 4000 rpm for 5 minutes. The aqueous phase was discarded and 5 mL of chloroform-methanol mixture were added. The tubes were shaken in a vortex for one minute. The lipid extract was transferred into clean test tubes. For the methylation a sample of 500 μ L of this extract was transferred to a tube. An acid transesterification (10) was carried out by adding 1 mL of Boron trifluoride solution and heating the tubes in a thermostatic bath set at 100 °C for 10 min, yielding the methyl esters of fatty acids (FAME's).

FAME's recovery was carried out by adding 1 mL of hexane and 1 mL of MilliQ water saturated with hexane to each methylation tube which was vigorously shaken in a vortex for 10 minutes; subsequently, tubes were centrifuged at 4000 rpm for 10 min, separating the organic phase, which contained FAME's. A second wash with 2 mL of hexane saturated MilliQ water was performed; tubes were shaken vigorously in a vortex for 10 minutes and centrifuged again at 4000 rpm for 10 min. The organic phase with FAME's was transferred to conical bottom injection vials. FAME's extracts were concentrated with a nitrogen flow to avoid oxidation. The resulting mixture was dissolved in 1 mL of dichloromethane. A volume injection of μ L was used for fatty acid identification and quantification.

Identification and quantification of fatty acids

Identification and quantification of FAME's was performed in a gas chromatograph (Perkin-Elmer, Autosystem XL model) equipped with a flame ionization detector (FID). A polar capillary column (SPTM -2560 75 m x 0.18 mm id x 0.14 μ m) was used. The temperature program of the column was: initial temperature 150°C,

increasing 4°C/min until 214°C, holding for 2 minutes, then increasing 2.5°C/min until 244°C and finally holding this temperature for 5 minutes.

Hydrogen was used as the carrier gas at a flow rate of 1 mL min⁻¹. Likewise, the FAME's identification was performed by comparison with retention times of a standard mixture of FAME's injected previously. The FAME's quantification was carried out by normalization and transformation of the area to mg per 100 g of sample.

Statistical analysis

The statistical analyses were carried out using the ANOVA and Duncan tests ($P \leq 0.05$) in the Statgraphics Centuryon XVI.I program. At least three replications for each analysis were done.

RESULTS AND DISCUSSION

Proximate analysis

The nutritional value of water based ice pops was not significant due to its low fat, protein, and fiber content. This is attributed to the kind of ingredients used in their preparation (water, sugar, corn syrup, flavorings and stabilizers). In the case of samples including natural fruits, the amount of fruit used is frequently too insignificant to influence the nutritional value in the final product. Carbohydrates content was similar for water and milk based ice pops.

Regarding milk based ice pops, all samples presented a high fat content (6.83-12.17%) and in some cases an interesting content of protein (3.55 and 4.20%) and fiber (8.81 and 3.2%) as in the case of nut and coconut ice pops (table 3). The fat content found was due to the kind of fruit and mix used in their preparation while protein was given mainly by the fruit.

Mineral content

Milk based popsicles had a calcium content between 17.46 and 45.78 mg/100 g which are lower than those reported for ice cream (80-138 mg/100 mg) (11). Several studies have demonstrated that dairy products are a good source of bioavailable calcium because of its lactose content, Ca/P ratio and to the Ca-casein complex. However, the samples of this study do not demonstrate this due to the use of vegetable oils and dairy solids in lower proportion.

Magnesium was found in the order of 4.95 and 17.66 mg/100 g; these values were closed to those reported recently for ice cream (9.3-11 mg/100g) (12). The high content of Mg in ice pops of this flavor was associated with the nut content since nuts are a source of this mineral (13, 14).

Phosphorus content was low (28.39-65.44mg/100)

compared with amounts reported for ice cream (45-150 mg/100) (11). P and Mg amounts determined could come from dairy solids and from salts as sodium and magnesium phosphate used as additive to improve texture of final products (15).

Fatty acids profile

The chromatogram of fatty acids standards is presented in figure 1. The fatty acids content (saturated, unsaturated and trans fatty acids) of ice pops analyzed are shown in table 4. Values were found in the range of 6.1-11.8%. Despite the total amount of ice pops showed a similar profile of fatty acids, their proportion of each acid was significantly different. In addition, the absence of linoleic and capric acids in some of them could point out that the mix used in their manufacturing process was a combination of different proportions of dairy and vegetable fat, depending on the flavor which was confirmed by the high proportion of palmitic acid and the presence of C18:1t. Figure 2 shows the chromatogram

of fatty acids profile of cookie ice pop which presented a higher amount of C18:1t. In the manufacturing process of the kind of cookies used in this sample formulation, partially hydrogenated fat is used (16).

A higher content of TFA was observed on pine nut and nut ice pops (31 and 21%, respectively). The C18:2t was predominant as well as in the strawberry-nut flavor. This reflected an elevated proportion of dairy fat in the mix used in the manufacturing of these samples.

CONCLUSION

It seems to be that ingredients such as nut, pine nut and coconut as well as the mix are mainly responsible for the fatty acid profiles on the final products and the mixes used in ice pop manufacturing are not entirely made with dairy fat but in combination with vegetable fat which was demonstrated with the absence, in some cases, of C18:1n-9 cis and trans, C18:3n3 and C18:0, which are fatty acids proper from cow milk (17). So, it becomes necessary to establish measurement controls

of raw materials used to produce mixes and ice pops since they are mass consumption products whose main market is children.

These results represent an important advance on the study of the TFA content in milky ice pops since there is little information about it. Due to the TFA implications on human health, their presence in the analyzed samples highlights the relevance of research in this field. This issue in México was considered by the Health Ministry which through the official norm NOM-043-SSA2-2005 (18) recommends to reduce fat/TFA consumption to prevent cardiovascular diseases. Regarding this, in 2008 the United States, through the Food and Drug Administration, began a promotion to make all food companies to include the TFA content legend in the labels of their products.

RESUMEN

Se determinó la composición química de paletas congeladas, en base agua y en base láctea, producidas por una microindustria en Hidalgo, México. Se analizaron

quince muestras de diferentes sabores. La composición proximal se llevó a cabo de acuerdo a las técnicas de la AOAC. La identificación y cuantificación de ácidos grasos en las paletas base láctea se realizó por cromatografía de gases con detector de ionización de llama. Las paletas base agua no presentaron un valor nutricional significativo. Con respecto a las paletas base láctea, se observaron contenidos de grasa de 6.83 a 12.7%; algunas presentaron valores interesantes de proteína (3.55 y 4.21%). El perfil de ácidos grasos reveló altos contenidos de ácidos grasos insaturados comparados con los saturados. Cinco de las siete paletas de base láctea analizadas presentaron ácidos grasos trans, representando 20-60% del total de ácidos grasos. Los análisis realizados han mostrado que las mezclas usadas para preparar las paletas son diferentes de acuerdo a su sabor, tipo y cantidad de fruta la cual modifica el valor nutricional y el nivel de ácidos grasos trans.

Palabras clave: composición química, ácidos grasos, cromatografía de gases, paletas congeladas.
