RESUMEN

En este trabajo consideramos una capa resistiva cilíndrica que transporta una corriente constante. Una batería genera la corriente en el centro del conductor. Estudiamos el comportamiento del potencial, campo eléctrico y cargas superficiales cerca de la batería.

Palabras clave: Potencial eléctrico, potencial cerca de la batería, cargas superficiales.

ABSTRACT

In this work we consider a long, resistive cylindrical shell carrying a steady current. A battery in the middle of the wire generates the current. We study the behavior of the potential, electric field and surface charges close to the battery.

Keywords: Electric potential, potential close to the battery, surface charges.

INTRODUCTION

There has been recently a great interest in the electric field outside resistive conductors carrying steady currents and a number of problems have been published in the literature: coaxial cables, [14], [8], [13], [1] and [2]; cylindrical shell with azimuthal current, [12], [10] and [16]; planes, [13]; twin leads, [15] and [4]; a long strip, [9]; and a long straight cylindrical conductor with longitudinal current, [5]. In this last case it has only been considered the region far from the battery. It was then found that the potential and surface charges vary linearly with the longitudinal component. Here we analyse the situation close to the battery in order to understand the behaviour of surface charges at a discontinuity in the potential.

We consider a hollow cylindrical shell of radius a and length ℓ with $\ell \gg a$. The shell has an uniform resistivity and carries a steady current I along the positive z direction which coincides with its axis. We suppose an idealized linear battery at $(\rho, \varphi, z) = (a, \varphi, 0)$, see Fig. 1, in analogy with Heald's treatment which considered a "line" battery at $(\rho, \varphi, z) = (a, \pi, z)$ driving current azimuthally in a uniform cylindrical resistive

sheet, [10]. We suppose a vacuum inside and outside the shell.

Fig. 1 A resistive cylindrical shell of radius a and length ℓ carrying a steady current in the z direction. There is a linear battery in $z=0$ generating a difference of potential of $2\phi_0$.

Ohm's law can be written as $\vec{J} = g\vec{E}$, where $\vec{J} = (I/2\pi at)\hat{z}$ is the volume current density ($t \ll a$ being the thickness of the shell), g the conductivity of the wire and $\vec{E}$ the driving electric field. We are supposing g and $\vec{J}$ as constants independent of φ , z and time. Therefore the same

must be true for $\vec{E}$. As $\vec{E} = -\nabla\phi$, ϕ being the potential, this implies that ϕ along the shell ($\rho = a$) must be a linear function of z . Supposing that the battery generates a potential difference of $2\phi_0$ between its two terminals located at $z \rightarrow 0^-$ and $z \rightarrow 0^+$, the linear potential at $\rho = a$ can be written as (Fig. 2):

$$\phi(a, \varphi, z < 0) = (\phi_R - \phi_L) \frac{z}{\ell} + \frac{\phi_R + \phi_L}{2} - \phi_0 \quad (1)$$

$$\phi(a, \varphi, z > 0) = (\phi_R - \phi_L) \frac{z}{\ell} + \frac{\phi_R + \phi_L}{2} + \phi_0 \quad (2)$$

Fig. 2 Potential along the shell.

Our goal is to find the potential and electric field at $\rho < a$ and at $\rho > a$ given the boundary conditions above. Then we can obtain the surface charge densities at the inner and outer surfaces of the shell.

This problem can be separated in two parts: a) the electrostatic situation of a cylindrical shell separated at $z = 0$ by a thin insulating barrier held at $-\phi_0$ for $z < 0$ and at ϕ_0 for $z > 0$; and b) a continuous linear potential $\phi(a, \varphi, z) = (\phi_R - \phi_L)z/\ell + (\phi_R + \phi_L)/2$ for $-\ell/2 \leq z \leq \ell/2$, see Fig. 3. The first part has been partially solved in [7] and the second one in [5]. Our intention is to deepen these studies in order to understand the behaviour close to the battery.

Fig. 3 The potential of Fig. 2 can be decomposed in two parts: the shell held at constant but discontinuous potentials (dashed lines), and the shell with a continuous potential varying linearly with the longitudinal coordinate (continuous line).

ELECTROSTATIC SOLUTION OF THE CYLINDRICAL SHELL WITH IS TWO HALVES HELD AT CONSTANT AND OPPOSITE POTENTIALS

Suppose two semi-infinite cylindrical shells, located at $z < 0$ and $z > 0$, see Fig. 1. The shell at $z < 0$ is held at the constant potential $-\phi_0$, while the shell at $z > 0$ is held at ϕ_0 , [17]. We can solve Laplace's equation, $\nabla^2\phi = 0$, in cylindrical coordinates using separation of variables in the form $\phi_{jk}(\rho, \varphi, z) = R_{jk}(\rho)\Phi_j(\varphi)Z_k(z)$, where the functions R_{jk} , Φ_j and Z_k obey the equations:

$$\begin{aligned} \frac{d^2 R_{jk}}{d\rho^2} + \frac{1}{\rho} \frac{dR_{jk}}{d\rho} - \left(k^2 + \frac{j^2}{\rho^2} \right) R_{jk} &= 0, \\ \frac{d^2 \Phi_j}{d\varphi^2} - j^2 \Phi_j &= 0, \\ \frac{d^2 Z_k}{dz^2} + k^2 Z_k &= 0 \end{aligned} \quad (3)$$

The final solution $\phi(\rho, \varphi, z)$ is a linear combination of all possible solutions $\phi_{jk}(\rho, \varphi, z)$.

Due to the rotational symmetry of the system, the solution will not depend on φ . This means $j = 0$ and $\Phi_j = \text{constant}$.

In this situation, the boundary conditions are anti-symmetric about the z coordinate, $\phi(a, \varphi, -z) = -\phi(a, \varphi, z)$, so the solution must also be anti-symmetric at all points: $\phi(\rho, \varphi, -z) = -\phi(\rho, \varphi, z)$ and $\phi(\rho, \varphi, 0) = 0$. Additionally, we must have a limited solution in both ρ and z coordinates, $|\phi(\rho, \varphi, |z| \rightarrow \infty)| \leq \phi_0 < \infty$ and $|\phi(\rho \rightarrow \infty, \varphi, z)| \rightarrow 0$. This leads to a solution for Z_k of the form: $Z_k(z) = \sin(kz)$. The equation for R_{jk} is the modified Bessel equation, whose solutions are $I_j(k\rho)$ (regular for $\rho \rightarrow 0$ and irregular for $\rho \rightarrow \infty$) and $K_j(k\rho)$ (regular for $\rho \rightarrow \infty$ and irregular for $\rho \rightarrow 0$), [6].

The general solution has then the form:

$$\phi(\rho \leq a, \varphi, z) = \int_0^\infty A_k I_0(k\rho) \sin(kz) dk \quad (4)$$

$$\phi(\rho \geq a, \varphi, z) = \int_0^\infty B_k K_0(k\rho) \sin(kz) dk \quad (5)$$

where the coefficients A_k and B_k must be determined from the boundary conditions. Eqs. (4) and (5) can be seen as a sine Fourier transform of a function Ψ :

$$\begin{aligned} \Psi(\rho, \varphi, k) &= \sqrt{\frac{2}{\pi}} \int_0^\infty \phi(\rho, \varphi, z) \sin(kz) dz = \\ &= \begin{cases} \sqrt{\pi/2} A_k I_0(k\rho), & \rho \leq a \\ \sqrt{\pi/2} B_k K_0(k\rho) & \rho \geq a \end{cases} \end{aligned} \quad (6)$$

Calculating Eq. (6) in $\rho = a$ and applying the boundary conditions $\phi(a, \varphi, z < 0) = -\phi_0$ and $\phi(a, \varphi, z > 0) = \phi_0$ yields the coefficients A_k and B_k :

$$A_k = \frac{2\phi_0}{\pi k I_0(ka)}, \quad B_k = \frac{2\phi_0}{\pi k K_0(ka)} \quad (7)$$

The final solution can be written as (see Appendix):

$$\phi(\rho \leq a, \varphi, z) = \frac{2\phi_0}{\pi} \int_0^\infty \frac{I_0(k\rho)}{I_0(ka)} \frac{\sin(kz)}{k} dk \quad (8)$$

$$= 2\phi_0 \frac{z}{|z|} \left[\frac{1}{2} - \sum_{n=1}^\infty \frac{J_0(x_n \rho/a)}{J_1(x_n)} \frac{e^{-x_n |z|/a}}{x_n} \right] \quad (9)$$

$$\phi(\rho \geq a, \varphi, z) = \frac{2\phi_0}{\pi} \int_0^\infty \frac{K_0(k\rho)}{K_0(ka)} \frac{\sin(kz)}{k} dk \quad (10)$$

In Eq. (9), x_n are the zeroes of the Bessel function of order zero, $J_0(x_n) = 0$, with $n = 1, 2, \dots$

SOLUTION FOR THE CYLINDRICAL SHELL WITH STEADY CURRENT AND BATTERY

Eqs. (13) and (14) of [5] give the solution of a conducting wire with radius a , length $\ell \gg a$ and carrying a steady current as:

$$\phi(\rho \leq a, \varphi, z) = (\phi_L - \phi_R) \frac{z}{\ell} + \frac{\phi_R + \phi_L}{2} \quad (11)$$

$$\begin{aligned} \phi(\rho \geq a, \varphi, z) &= (\phi_L - \phi_R) \frac{\ln(\ell/\rho)}{\ln(\ell/a)} \frac{z}{\ell} + \\ &+ \frac{\phi_R + \phi_L}{2} \frac{\ln(\ell/\rho)}{\ln(\ell/a)} \end{aligned} \quad (12)$$

The solution of the problem with the battery is the sum of Eqs. (8) and (11) for the region inside the shell, and the sum of Eqs. (10) and (12) for the region outside the shell, namely:

$$\begin{aligned} \phi(\rho \leq a, \varphi, z) &= \frac{2\phi_0}{\pi} \int_0^\infty \frac{I_0(k\rho)}{I_0(ka)} \frac{\sin(kz)}{k} dk + \\ &+ (\phi_L - \phi_R) \frac{z}{\ell} + \frac{\phi_R + \phi_L}{2} \end{aligned} \quad (13)$$

$$\begin{aligned} \phi(\rho \geq a, \varphi, z) &= \frac{2\phi_0}{\pi} \int_0^\infty \frac{K_0(k\rho)}{K_0(ka)} \frac{\sin(kz)}{k} dk + \\ &+ (\phi_L - \phi_R) \frac{\ln(\ell/\rho)}{\ln(\ell/a)} \frac{z}{\ell} + \frac{\phi_R + \phi_L}{2} \frac{\ln(\ell/\rho)}{\ln(\ell/a)} \end{aligned} \quad (14)$$

Fig. 4 shows the equipotentials with $\phi_L = \phi_0$, $\phi_R = -\phi_0$ and $\ell/a = 10$.

Fig. 4 Equipotentials of conducting wire close to $z=0$. This is a plot of Eqs. (13) and (14) with $\phi_L = -\phi_R = \phi_0$ and $\ell/a = 10$. There is a steady current flowing along the positive z direction.

The electric field $\vec{E}$ can be obtained from the potential utilizing the relation $\vec{E} = -\nabla\phi$. This yields:

$$\begin{aligned} \vec{E}(\rho < a, \varphi, z) = & -\frac{2\phi_0}{\pi} \\ & \left[\rho \int_0^\infty \frac{I_1(k\rho)}{I_0(ka)} \sin(kz) dk + z \int_0^\infty \frac{I_0(k\rho)}{I_0(ka)} \cos(kz) dk \right] + \\ & + z \frac{\phi_L - \phi_R}{\ell} \end{aligned} \quad (15)$$

$$\begin{aligned} \vec{E}(\rho > a, \varphi, z) = & \frac{2\phi_0}{\pi} \cdot \\ & \left[\rho \int_0^\infty \frac{K_1(k\rho)}{K_0(ka)} \sin(kz) dk - z \int_0^\infty \frac{K_0(k\rho)}{K_0(ka)} \cos(kz) dk \right] + \\ & + \left\{ \frac{-1}{\ln(\ell/a)} \frac{\rho}{\rho} \left[(\phi_L - \phi_R) \frac{z}{\ell} - \frac{\phi_R + \phi_L}{2} \right] + \right. \\ & \left. + z \frac{\phi_L - \phi_R}{\ell} \frac{\ln(\ell/\rho)}{\ln(\ell/a)} \right\} \end{aligned} \quad (16)$$

The surface charge distribution $\sigma(a, \varphi, z)$ can be found by applying Gauss' law and choosing a gaussian surface surrounding a small piece of the conductor surface. In the limit of an infinitesimal surface this yields the

internal and external densities of surface charge as given by, respectively (where $\epsilon_0 = 8.85 \times 10^{-12} \text{ C}^2 \text{ N}^{-1} \text{ m}^{-2}$):

$$\begin{aligned} \sigma_{\text{in}}(a^-, \varphi, z) = & -\lim_{\rho \rightarrow a} \epsilon_0 E_\rho(\rho < a, \varphi, z) = \\ = & \frac{2\phi_0 \epsilon_0}{\pi} \int_0^\infty \frac{I_1(ka)}{I_0(ka)} \sin(kz) dk = \\ = & \frac{2\phi_0 \epsilon_0}{a} \frac{z}{|z|} \sum_{n=1}^\infty e^{-x_n |z|/a} \end{aligned} \quad (17)$$

$$\begin{aligned} \sigma_{\text{ex}}(a^+, \varphi, z) = & \lim_{\rho \rightarrow a} \epsilon_0 E_\rho(\rho > a, \varphi, z) = \\ = & \frac{2\phi_0 \epsilon_0}{\pi} \int_0^\infty \frac{K_1(ka)}{K_0(ka)} \sin(kz) dk + \\ & - \frac{\epsilon_0 (\phi_L - \phi_R)}{a \ell \ln(\ell/a)} z + \frac{\epsilon_0 (\phi_R + \phi_L)}{2a \ln(\ell/a)} \end{aligned} \quad (18)$$

Fig. 5 shows these normalized densities of surface charge as a function of z/a . Both of them diverge to infinity when $|z/a| \ll 1$. For $|z/a| \gg 1$ the internal density of surface charge goes to zero faster than the external one.

Fig. 5 Densities of surface charge as a function of the z (longitudinal) coordinate for a resistive hollow cylindrical shell carrying a steady current. The dashed (continuous) lines is the normalized internal (external) density of surface charges. Both densities are normalized by the internal density ($\rho = a^-$) at $z = a$

DISCUSSION

Jefimenko and Heald considered a similar geometry (resistive cylindrical shell of radius a coaxial with the z axis) but carrying a steady azimuthal current, [18], [10] and [16]. A line battery located at $(\rho, \varphi, z) = (a, \pi, z)$ had its terminals at potentials $\pm\phi_0$. They found equal internal and external surface charge densities given by:

$$\sigma_{\text{in}} = \sigma_{\text{ex}} = \frac{\varepsilon_0 \phi_0}{\pi a} \tan \frac{\varphi}{2}$$

For angles close to the battery, $\varphi = (\pi \pm \delta)$ rad, with $0 < \delta \ll \pi$, this reduces to $\sigma_{\text{in}} = \sigma_{\text{ex}} \approx \pm 2\varepsilon_0 \phi_0 / \pi a \delta$. This indicates that σ diverges inversely proportional to the distance $d = a\delta$ to the battery.

A numerical fitting of Eq. (18) with the function:

$$\sigma_{\text{in}}(|z| \ll a) = \frac{2\varepsilon_0 \phi_0 \alpha}{\pi z} \quad (20)$$

for the region $|z|/a < 10^{-2}$ yields the value of the unknown dimensionless constant α as given by $\alpha = 0.998$. This indicates that α should be exactly equal to 1, as expected.

We can also approximate the summation of Eq. (18) by supposing that the zeroes x_n of the Bessel function of order zero, $J_0(x_n) = 0$, are evenly spaced. That is, supposing $x_n \approx nx_0$, where $x_0 = 3.12988$ and $n = 1, 2, \dots$. Using the known series:

$$\sum_{n=1}^{\infty} x^n = \frac{x}{1-x}, \quad (21)$$

we obtain:

$$\begin{aligned} \sum_{n=1}^{\infty} e^{-x_n |z|/a} &\approx \sum_{n=1}^{\infty} e^{-nx_0 |z|/a} = \\ &= \sum_{n=1}^{\infty} \left(e^{-x_0 |z|/a} \right)^n = \frac{1}{e^{-x_0 |z|/a} - 1} \approx \frac{a}{x_0 |z|} \end{aligned} \quad (22)$$

where in the last approximation the observation point is close to the battery, $|z|/a \ll 1$. Eq. (18) can be written in this approximations as:

$$\sigma_{\text{in}}(a^-, \varphi, |z| \ll a) \approx \frac{2\varepsilon_0 \phi_0}{x_0 z} \quad (23)$$

Eqs. (20) and (23) differ by 0.6%.

A similar result can be obtained by approximating the integrals that appear in Eqs. (17) and (18) for the region $|z|/a \ll 1$. For Eq. (17), we divide the integral in two regions, $0 < k < 1/a$ and $1/a < k < \infty$. Defining $x \equiv ka$ and utilizing $\sin \alpha \approx \alpha$ for $\alpha \ll 1$ rad yields:

The functions $I_\nu(x \ll 1)$ and $I_\nu(x \gg 1)$ can be approximated as, [AW95, pp. 664–671]:

$$\begin{aligned} \int_0^\infty \frac{I_1(ka)}{I_0(ka)} \sin(kz) dk &= \frac{1}{a} \int_0^\infty \frac{I_1(x)}{I_0(x)} \sin\left(\frac{xz}{a}\right) dx = \\ &= \frac{1}{a} \int_0^1 \frac{I_1(x)}{I_0(x)} \sin\left(\frac{xz}{a}\right) dx + \frac{1}{a} \int_1^\infty \frac{I_1(x)}{I_0(x)} \sin\left(\frac{xz}{a}\right) dx \\ &\approx \frac{1}{a} \int_0^1 \frac{I_1(x)}{I_0(x)} \frac{xz}{a} dx + \frac{1}{a} \int_1^\infty \frac{I_1(x)}{I_0(x)} \sin\left(\frac{xz}{a}\right) dx \end{aligned} \quad (19)$$

$$I_\nu(x \ll 1) \approx \left(\frac{x}{2}\right)^\nu \left[\frac{1}{\Gamma(\nu+1)} + \left(\frac{x}{\nu}\right)^2 \frac{1}{\Gamma(\nu+2)} \right], \quad (24)$$

$$I_\nu(x \gg 1) \approx \frac{e^x}{\sqrt{2\pi x}} \left(1 + \frac{1-4\nu^2}{8x} \right) \quad (25)$$

With these results we can neglect the first integral of Eq. (19) and approximate the result as:

$$\begin{aligned} \int_0^\infty \frac{I_1(ka)}{I_0(ka)} \sin(kz) dk &\approx \frac{1}{a} \int_1^\infty \sin\left(\frac{xz}{a}\right) dx \approx \\ &\approx \frac{1}{a} \int_0^\infty \sin\left(\frac{xz}{a}\right) dx \approx \frac{1}{z} \end{aligned} \quad (26)$$

where in the last approximation we extended the integral from 0 to ∞ , because the integral from 0 to 1 is also negligible in the approximation $|z|/a \ll 1$. To arrive at the final value of $1/z$ we utilized that the sequence $\int_0^N \sin(kx) dx = (1 - \cos(kN))/k$ diverges as $N \rightarrow \infty$, but it is weakly convergent for a suitable chosen set of test functions $g(k)$ defined for $0 \leq k < \infty$, [20].

Analogously for Eq. (18), the approximation of the integral yields:

$$\int_0^{\infty} \frac{K_1(ka)}{K_0(ka)} \sin(kz) dk \approx \frac{1}{z}. \quad (27)$$

Eqs. (17) and (18) can be written in this approximations as:

$$\begin{aligned} \sigma_{\text{in}}(a^-, \varphi, |z| \ll a) &= \frac{2\varepsilon_0 \phi_0}{\pi z}, \\ \sigma_{\text{ex}}(a^+, \varphi, z) &= \frac{2\phi_0 \varepsilon_0}{\pi z} - \frac{\varepsilon_0(\phi_L - \phi_R)}{a \ell \ln(\ell/a)} z + \\ &+ \frac{\varepsilon_0(\phi_R + \phi_L)}{2a \ln(\ell/a)} \end{aligned} \quad (28)$$

For a long cylindrical conductor ($\ell \gg a$), Eqs. (28) and (29) show that the surface charges diverge in the vicinity of the battery as a/z when $z \rightarrow 0$. Additionally, in the vicinity of the battery the electrostatic contribution is greater than the terms that maintain the current flow. This implies that the situations with and without current have little difference in the surface charge distribution, although they correspond to different phenomena, as had already been observed by Jackson, [11].

The total surface charges for the symmetric case $\phi_L = -\phi_R = \phi_0$ can be written as:

$$\begin{aligned} \sigma(a, z) &= \sigma_{\text{in}}(a, z) + \sigma_{\text{ex}}(a, z) = \\ &= \frac{2\varepsilon_0 \phi_0}{\pi} \int_0^{\infty} \left[\frac{I_1(ka)}{I_0(ka)} + \frac{K_1(ka)}{K_0(ka)} \right] \sin(kz) dk + \\ &- \frac{2\varepsilon_0 \phi_0}{a \ell \ln(\ell/a)} z \end{aligned} \quad (30)$$

We want to find the position z_0 where the surface charge distribution is null, $\sigma(a, z_0) = 0$. In the interval $1 \leq \ell/a \leq 100$, equating Eq. (31) to zero yields $z_0/a = 0.0890 + 0.05068 \ell/a$, or $z_0 \approx 0.507 \ell$ for $\ell/a \gg 1$. Although our solution is valid only for $z \ll \ell/2$ (we have neglected border effects), we found that the surface charges are null at the extremities of the cylindrical shell. This can be interpreted as follows: if we bend the wire, so that the extremities at $z = \pm \ell/2$ touch each other, the surface charges at that position should be null. This is very reasonable.

ACKNOWLEDGEMENTS

The authors wish to thank Fapesp (Brazil) for financial support to DRCC/IFGW/Unicamp in the past few years. They thank also Regina Fonseca Avila for useful suggestion related with the integration in the complex plane. One of the authors (JAH) wishes to thank CNPq (Brazil) for financial support.

APPENDIX

Calculation of the integral of Eq. (8). As it is an even function of k it can be written as:

$$\begin{aligned} \int_0^{\infty} \frac{I_0(k\rho)}{I_0(ka)} \frac{\sin(kz)}{k} dk &= \frac{1}{2} \int_{-\infty}^{\infty} \frac{I_0(k\rho)}{I_0(ka)} \frac{\sin(kz)}{k} dk = \\ &= \frac{1}{2i} \int_{-\infty}^{\infty} \frac{I_0(k\rho)}{I_0(ka)} \frac{e^{ikz}}{k} dk \end{aligned} \quad (31)$$

The integral above is part of a contour integral on the complex variable k :

$$I = \oint_C \frac{I_0(k\rho)}{I_0(ka)} \frac{e^{ikz}}{k} dk, \quad (32)$$

with an appropriate contour C . The integrand has a simple pole in $k_0 = 0$ and infinite simple poles in k_n such that:

$$I_0(k_n a) = 0 \quad \rightarrow \quad J_0(x_n) = 0, \quad (33)$$

where $x_n = -ik_n a$ are the zeroes of the function $J_0(x)$: $x_1 = 2.4048$, $x_2 = 5.5201$, ... and $n = 1, 2, \dots$. As $e^{ikz} = e^{i\alpha z - \beta z}$, for $k = \alpha + i\beta$ (α and β being real numbers), the integral converges for $\beta z > 0$. We choose a contour of the type shown in Fig. 6 for $z > 0$. The contour integral can thus be divided in three parts: along the real k axis, along the path C_r and along the path C_R . The integral along the path C_r is given by:

$$\begin{aligned} \lim_{r \rightarrow 0} \int_{C_r} \frac{I_0(k\rho)}{I_0(ka)} \frac{e^{ikz}}{k} dk &= \\ &= \lim_{r \rightarrow 0} \int_{\pi}^0 \frac{I_0(r e^{i\varphi} \rho)}{I_0(r e^{i\varphi} a)} \frac{\exp(ikr e^{i\varphi})}{r e^{i\varphi}} i r e^{i\varphi} d\varphi = -i\pi \end{aligned} \quad (34)$$

Fig. 6 Contour to calculate the integral of Eq. (8), for $z > 0$. For $z < 0$ we choose a symmetrical contour reflected at the horizontal (real k) axis

The integral along the path C_R is limited, and vanishes for $R \rightarrow \infty$:

$$\lim_{R \rightarrow \infty} \left| \int_{C_R} \frac{I_0(k\rho) e^{ikz}}{I_0(ka) k} dk \right| \leq \lim_{R \rightarrow \infty} \int_{C_R} \left| \frac{e^{ikz}}{k} \right| dk = 0 \quad (35)$$

Using Cauchy's theorem, the integral I is given by:

$$\begin{aligned} \lim_{\substack{r \rightarrow 0 \\ R \rightarrow \infty}} \oint_C \frac{I_0(k\rho) e^{ikz}}{I_0(ka) k} dk &= \int_{-\infty}^{\infty} \frac{I_0(k\rho) e^{ikz}}{I_0(ka) k} dk - i\pi = \\ &= 2i\pi \sum_{n=1}^{\infty} \text{Res}(k_n) = 2i\pi \sum_{n=1}^{\infty} \frac{I_0(k_n \rho) e^{ik_n z}}{I_1(k_n a) a k_n} \end{aligned} \quad (36)$$

where $\text{Res}(k_n)$ is the residue of the integrand in $k = k_n = ix_n/a$. In the equation above we utilized the relation $I_0'(x) = I_1(x)$ involving modified Bessel functions, where $I_0'(x) \equiv dI_0(x)/dx$. Therefore the integral of Eq. (8) for $z > 0$ is given by (using the relation $J_\nu(ix) = i^\nu I_\nu(x)$):

$$\int_0^\infty \frac{I_0(k\rho) \sin(kz)}{I_0(ka) k} dk = \frac{\pi}{2} - \pi \sum_{n=1}^{\infty} \frac{J_0(x_n \rho/a) e^{-x_n z/a}}{J_1(x_n) x_n} \quad (37)$$

Analogously, the integral of Eq. (8) for $z < 0$ is given by:

$$\int_0^\infty \frac{I_0(k\rho) \sin(kz)}{I_0(ka) k} dk = -\frac{\pi}{2} + \pi \sum_{n=1}^{\infty} \frac{J_0(x_n \rho/a) e^{x_n z/a}}{J_1(x_n) x_n} \quad (38)$$
